

Chinook Digital Media: Customer and Revenue Analytics

Executive Summary

Daniel Matel-Okoh | dmatelok@gmail.com | github.com/dmatelokoh/chinook-analytics-portfolio

OVERVIEW

An end-to-end analytics portfolio built on the Chinook digital media database: three SQL case studies, a multi-part Python investigation, and three interactive Tableau dashboards. Each phase builds on the last. Every analysis comes back to the same question: where should a marketing team spend its budget, and why?"

KEY FINDINGS

1. Three markets carry the business.

The USA, Canada, and France account for 44% of total revenue across 24 countries. The bottom 15 markets each depend on a single customer. Losing one means that market goes to zero. The recommendation: grow mid-tier markets (Germany, UK, Brazil) to reduce geographic concentration.

2. Customer tiers are compressed because the product pricing is too narrow.

72% of revenue sits in a single value tier (Silver). The cause is structural: with tracks priced at \$0.99 and \$1.99, there isn't enough price variance to create meaningful spend separation. Segmentation works, but upsell opportunities require product or pricing changes.

3. Four genres drive 73.5% of revenue, and the trend data shows they're still growing.

Rock, Latin, Metal, and Alternative & Punk dominate the catalog and have grown consistently since 2019, with Rock accelerating sharply through 2024. Concentration is a strength here, not a risk. Sci Fi & Fantasy leads in catalog efficiency (\$1.53/track vs. \$0.64 for Rock), which suggests unmet demand worth investigating.

4. Customers buy on a ~32-day cycle, and the intervention window is narrow.

The median repurchase interval is 32 days with high natural variance. 57.6% of repeat purchases happen within 6 weeks. A proactive engagement campaign at 14–21 days and a win-back trigger at 40–100 days would cover the two highest-leverage windows in the customer lifecycle.

5. Retention follows the same curve regardless of when a customer joined.

Every quarterly cohort decays at the same rate (± 7 percentage points across 26 cohorts over 6 years). The steepest drop is at Q+4 (-14.5pp). Half of all churn happens by Q+5. Retention investment should target the first 12 months, where the highest share of churn is still preventable.

TOOLS & APPROACH

SQL: Revenue segmentation, CLV tiering, catalog benchmarking (CTEs, window functions, multi-table joins)

Python: Purchase timing analysis, cohort retention, time series (pandas, matplotlib, seaborn)

Tableau: Three interactive dashboards with cross-filtering, published to Tableau Public AI
